Kutztown University

New Process

- ▶ `fork()`
- ▶ Copies existing process
- ▶ Now TWO processes, so two return values!!
 - ▶ Parent - PID of child
 - ▶ Child - 0
- ▶ Data, code, stack and heap are copied**
 - ▶ Heap will depend on OS implementation; may be shared heap

Process

```
pid_t npid;  
npid = fork();
```

Shared File Descriptors

- ▶ Child inherits parent's file descriptor table
- ▶ Shared file offsets
- ▶ Example: `forkOutput.c`

OS Efficiency

- ▶ Share code area → WHY?
- ▶ Copy-On-Write (COW)
- ▶ Example

Processes End

- ▶ *Orphan* process
- ▶ *Zombie* process

- ▶ `wait()`
- ▶ `waitpid()`
- ▶ `wait3()`

New Process in Other Languages

▶ Python

- ▶ `fork()`
- ▶ `os.wait()`

▶ Java

- ▶ Don't create new processes
- ▶ `ProcessBuilder` - similar
- ▶ `Fork/Join` - threads

Pointers with fork()

- ▶ Parent's address space copied
- ▶ OS implementation of heap is irrelevant

- ▶ Example
 - ▶ Value vs. address

exec() family of calls

- ▶ Replace an existing process

- ▶ execl()

- ▶ execv()

- ▶ execl_e()

- ▶ execlp()

- ▶ execvp()

- ▶ execve()

- ▶ Example

- ❖ p - uses PATH

- ❖ l - list of arguments

- ❖ v - vector (array) of arguments

- ❖ e - array of environment variables
